

TCX Three Candle EA and Web Controller

Complete user guide for the trading EA, dashboard, controls, trade management, alerts, and multi-account workflow.

This document explains what the system does in plain trading language. It avoids programming details and focuses on how a trader should understand and operate the EA and website.

Area	What it covers
EA	Three-candle model detection, BUY/SELL arming, risk-based entry, SL/TP handling, second entry, partials, break even, first-trade trailing, close controls, live panel.
Website	Live account dashboard, trade buttons, risk controls, positions, closed trade history, market structure, funding-rule checks, Telegram settings, and EA connection credentials.
Accounts	Each connected MT5 account uses its own EA credentials. The current design supports many EAs per website user, and can be extended into controller groups and copy trading.

1. Big Picture

The TCX system has two parts: an MT5 Expert Advisor that sits on a chart and manages trades, and a web dashboard that lets the user monitor and control the EA from the browser. The EA does the actual trading work inside MT5. The website is the command center and live dashboard.

The system is designed for controlled execution. The user arms a direction, the EA waits for a valid completed three-candle model, then it places the trade with the configured risk, stop loss, and target. It does not need the user to manually calculate lot size each time.

Main promise of the system

- Wait for a valid three-candle setup before entry.
- Enter only after the third candle is closed, not while the candle is still forming.
- Use risk money to calculate trade size instead of guessing lot size.
- Manage SL, TP, partial close, break even, second entry, and first-trade trailing from one place.
- Show live account state, open trades, history, structure checks, and rule checks on the website.

Important operating rule

The EA should be tested on demo first. A live account should only be used after the trader confirms that entry, close, break even, partials, second entry, trailing, web commands, and alerts all behave correctly.

2. The Three-Candle Trading Models

The EA watches for three-candle formations. A trade is allowed only when the complete model is present and the third candle is closed. The system supports BUY and SELL versions of the same idea.

Model family 1 - Standard three-candle model

- BUY: candle 1 is bullish, candle 2 is bearish, and candle 3 is bullish.
- SELL: candle 1 is bearish, candle 2 is bullish, and candle 3 is bearish.
- The third candle must close in a way that confirms the model direction.
- The model is checked on closed candles only, so a candle that reverses before close will not be treated as a completed signal.

Model family 2 - Strong swing model

- BUY: the third candle sweeps lower and then closes with stronger upside confirmation.
- SELL: the third candle sweeps higher and then closes with stronger downside confirmation.
- This model is built for situations where price creates a sweep and then closes strongly back in the trade direction.

Model family 3 - Weak swing model

- BUY: the third candle still shows a lower sweep, but the close only needs to reclaim the model reference level.
- SELL: the third candle still shows a higher sweep, but the close only needs to reject back below the model reference level.
- This model gives a second type of swing confirmation while still requiring the candle to close first.

Buy and sell behavior

Direction	What the EA wants to see
BUY	A completed bullish setup. The EA waits for the third candle to close, calculates the model stop loss below the setup, and places the BUY if all risk and trading checks pass.
SELL	A completed bearish setup. The EA waits for the third candle to close, calculates the model stop loss above the setup, and places the SELL if all risk and trading checks pass.

Quick model checklist	Why it matters
Entry checklist	The setup must be complete, the third candle must be closed, the direction must match the armed mode, and the EA must not already be managing a locked trade cycle.
Buy checklist	The completed candles must show bullish confirmation, model stop below the structure, valid broker stop distance, and acceptable trade conditions.
Sell checklist	The completed candles must show bearish confirmation, model stop above the structure, valid broker stop distance, and acceptable trade conditions.
No candle-close, no entry	If the candle looks good while open but reverses before close, the EA should ignore it because the model is not completed.
One signal, one entry cycle	The EA remembers the signal candle and avoids repeating the same completed

Trading reminder: the model is only a decision filter. Account risk, spread, news conditions, broker rules, and the trader's plan still matter before using live money.

3. Entry Timing and Arming

The EA is controlled by arming modes. Arming means the user tells the EA what kind of setup to wait for. It does not mean the EA enters immediately.

Control	Meaning
ARM BUY	The EA waits for the next valid BUY model. It enters only after the third candle of that model has closed.
ARM SELL	The EA waits for the next valid SELL model. It enters only after the third candle of that model has closed.
AUTO ARM	The EA watches for either BUY or SELL models and chooses the next valid direction when the model completes.
CANCEL	Turns off waiting mode. No new model entry will be taken until the user arms again.

Fresh setup protection

When the user arms the EA, it is meant to wait for a fresh setup after that point. The EA is designed to avoid repeatedly entering the same signal candle. It also avoids using a candle that is still open.

Third candle close rule

A model is valid only after candle 3 closes. If candle 3 looks valid during the candle but reverses before close, the EA should not enter from that unfinished candle.

4. Risk, Stop Loss, and Take Profit

The EA uses money risk as the main risk setting. For example, if the account currency is USD and risk is set to 100, the EA calculates a trade size that risks about 100 USD to the stop loss, before broker rounding and margin limits.

Setting	Plain meaning
Risk Money	How much account currency the user wants to risk on the trade.
RR Target	The reward target compared with the stop distance, such as 1:3.
Lot Size	Can be shown and adjusted, but the risk setting is the main sizing guide.
Stop Loss	Placed from the model structure, with optional extra space for spread and protection.
Take Profit	Placed from the stop distance and the selected reward target.

Protection behavior

- The EA checks whether the SL and TP are valid for the broker before and after opening the trade.
- If a broker refuses SL/TP on first send, the EA can retry the order and then apply protection after the position appears.
- If protection cannot be applied and protection safety is enabled, the EA can close the unprotected trade.

5. Trade Management Controls

Button	What it does
CLOSE	Closes the current matching EA position.
ALL	Closes all matching EA positions on that chart/symbol/magic.
50%	Closes half of the current position volume when possible.
BE	Moves the stop loss to break even with the configured small extra buffer.
PART ON/OFF	Turns automatic partial close monitoring on or off.
2ND ON/OFF	Turns the second-entry feature on or off for the current trade cycle.
1TR ON/OFF	Turns first-trade M5 trailing on or off.

6. Partial Close System

The partial close system lets the EA book parts of the trade at selected reward levels. The user can set three partial levels and percentages. The common setup is PC1, PC2, and PC3, with percentages that total the intended amount to close over time.

- PC1 can close a chosen percentage when the trade reaches the first reward level.
- PC2 can close another percentage at the second reward level.
- PC3 can close the remaining selected percentage at the third reward level.
- If the volume is too small for the broker minimum, the EA skips or adjusts safely rather than forcing an invalid close.

7. Second Entry at 50 Percent Loss Area

The second-entry feature is an add-on entry after the first trade moves against the entry by the configured loss amount. In the current setup this is used around the 50 percent loss area, meaning the trade has moved about half of the original risk against the first entry.

How it works

- The first trade opens normally from the three-candle model.
- If second entry is ON and the first trade reaches the configured loss trigger, the EA can open one second entry in the same direction.
- The second entry uses the same stop loss and take profit levels as the first trade.
- The second entry is allowed only one time for that trade cycle.
- After the second entry is placed, the second-entry toggle turns OFF for that cycle so it cannot keep adding more entries.

Cancel behavior at profit

If the first trade reaches the configured positive reward level before the second entry is used, the second entry is blocked for that cycle. The EA can also move the first trade to break even at that point, depending on the protection result.

8. First-Trade M5 Trailing

The first-trade trailing feature is separate from the second trade. It is designed to trail only the original first position, not the second-entry position.

BUY trailing rule

- Trailing starts only after the second entry is done.
- The first trailing move waits for a closed M5 candle above the first trade entry price.
- When that happens, the first trade stop loss is trailed to that M5 candle low.
- After trailing is active, the next trail happens only when a new M5 candle closes above the previous M5 candle high.
- If that confirmation does not happen, the stop loss is not moved.

SELL trailing rule

- The SELL side mirrors the BUY side.
- The first trailing move waits for a closed M5 candle below the first trade entry price.
- The stop loss is trailed to that M5 candle high.
- After trailing is active, the next trail requires a new M5 close below the previous M5 candle low.

Important

First-trade trailing does not change the second-entry trade. It targets only the original first trade so the second trade keeps its own SL/TP plan.

9. EA Live Panel

The EA panel inside MT5 gives the trader a compact command and monitoring surface directly on the chart.

Panel area	What it shows
Status	Whether the EA is waiting, armed, managing a position, or blocked by a condition.
Daily loss lock	Shows daily loss lock status based on the configured daily risk limits.
Candle structure	Shows whether selected timeframes are currently above or below their open.
Sweep structure	Shows high and low sweep status for selected timeframes.
Arming controls	BUY, SELL, and AUTO waiting controls.
Quality score	A quick score showing how many key readiness checks are aligned.
Risk management	Lot, risk money, reward target, and estimated risk guidance.
Trade mode	Safe/advanced controls, partials, second entry, and first-trade trailing toggles.
Message area	Latest EA message such as entry sent, SL moved, command processed, or warning.

10. Website Dashboard

The website is the remote command center. It connects to one or more EA instances and shows the selected EA account in real time.

Website area	Purpose
Top account selector	Selects which EA/account is currently shown and controlled.
Status hero	Shows online state, symbol, arm mode, positions, spread, second-entry state, first-trail state, and quality.
Account stats	Shows balance, equity, open profit/loss, risk per trade, daily result, and other account-level numbers.
Trade controls	Sends ARM BUY, ARM SELL, AUTO ARM, CANCEL, PING, close, break even, and close-all commands.
Risk and partials	Sets risk money, lot display, reward target, partial percentages, second entry, and first-trail toggles.
Positions	Shows live open positions, volume, RR, profit/loss, entry, SL, and TP.
Market structure	Shows candle structure and sweep structure in the browser.
Command log	Shows recent commands and whether they are waiting, sent, done, failed, or expired.
Trade history	Shows closed trade history, wins, losses, and net result.
Rules page	Shows funding-rule checks based on live account and trade data.
Settings	Controls Telegram alert setup and account-level website settings.

11. Connecting an EA to the Website

Each MT5 connection needs its own credentials from the website. These credentials identify that exact EA/account connection.

Credential	Plain meaning
Functions URL	The website command and state address used by the EA.
EA ID	The unique identity of that EA connection.
EA Token	The private key that allows that MT5 EA to prove it belongs to the user.

Recommended account setup

- Create one EA connection for each MT5 account or chart that should be controlled separately.
- Paste that EA connection into only one MT5 EA/account unless intentionally building a shared setup.
- Keep the token private. If a token is exposed, disable or regenerate that connection.
- Use clear names such as Main Account, Prop Account 1, Prop Account 2, or XAUUSD M5 Account.

12. Multi-Account and Copy Trading Direction

The current website already supports many EA records under one user account. The clean long-term copy trading design is to group multiple MT5 accounts under one controller.

Controller group idea

- A controller is the master control page where the trader clicks ARM BUY, ARM SELL, risk settings, close, break even, second entry, and trailing.
- Under the controller, the user can add many MT5 accounts. Each account receives its own EA ID and token.
- One command from the controller can be sent to all selected online accounts.
- Each account still reports its own balance, equity, positions, risk, trade history, and status.

Copy trading idea

- A master trader can own a controller group.
- A follower can be invited and can connect their own MT5 account.
- The follower must turn auto-copy ON before commands are copied.
- The follower can set personal risk rules, such as same risk, smaller risk, balance percentage, fixed amount, or a multiplier.
- The follower can disable copying, remove access, or set maximum risk limits.

Safe copy trading rule

Copy trading should copy the trading intention and risk rule, not blindly copy lot size. Different accounts can have different balances, symbols, broker rules, spreads, and lot limits.

13. Telegram Alerts

Telegram alerts let the user receive important account and EA updates outside the website.

- Trade opened notifications can include entry, SL, TP, symbol, account, and direction.
- SL and TP hit notifications help the user track outcomes.
- Command sent, done, and failed alerts show whether website actions reached the EA.

- EA online and offline alerts show connection health.
- The user can choose which alert types are enabled.

14. Funding Rule Checks

The website includes a rule-checking area for funding-style account rules. It uses the latest account and trade data to show whether objectives look safe, close to risk, or breached.

- Balance, equity, open P/L, and closed trade history are used to calculate rule progress.
- The rules page is a guide for monitoring, not a replacement for checking the funding company rules directly.
- Rules can change, so the trader should verify official rules before making high-stakes decisions.

15. Normal Operating Workflow

Step	Action
1	Connect the EA to the website and confirm it shows online.
2	Set risk money and reward target.
3	Choose whether partials, second entry, and first-trade trailing should be ON or OFF.
4	Click ARM BUY, ARM SELL, or AUTO ARM.
5	Wait for the third candle of a valid model to close.
6	EA opens the trade if all checks pass.
7	Manage using close, close 50%, break even, partials, second entry, and first-trade trailing.
8	Review live position, command log, trade history, and alerts.

16. Safety Checklist

- Use demo first after every new feature or setting change.
- Confirm the EA only enters after the third candle closes.
- Confirm SL and TP appear correctly after entry.
- Confirm second entry uses the same SL and TP as the first trade and only fires once.
- Confirm first-trade trailing moves only the first trade and does not alter the second trade.
- Confirm close, close 50%, break even, partials, and website commands work before live use.
- Keep EA tokens private and disable any connection that is no longer used.

17. Summary

The TCX Three Candle EA and website are built as a controlled trading command system. The EA waits for completed three-candle models, sizes trades by risk money, manages SL and TP, supports second entry and first-trade trailing, and reports everything back to the website. The website gives the user a browser-based command center with live state, controls, history, rules, Telegram alerts, and the foundation for multi-account or copy-trading control.

The main principle is simple: one clean model, one controlled entry after candle close, risk-first trade sizing, and clear management from both MT5 and the website.
